PATENT

**IN THE UNITED STATES PATENT AND TRADEMARK OFFICE**

**FORENSIC COMMUNICATION APPARATUS AND METHOD**

**TECHNICAL FIELD OF THE INVENTION**

**[0001]** This invention is related in general to information transmission systems and, more particularly, to an information transmission system that is operable to be stored at a remote location as a secure file in a trusted environment.

**CROSS-REFERENCE TO RELATED APPLICATIONS**

**[0002]** This application claims the benefit of Provisional Patent Application No. 60/414,449, filed on September 30, 2002.

## BACKGROUND OF THE INVENTION

[0003] With the popularity of wireless “digital” computing devices, such as, Personal Digital Assistants (PDA’s) cell phones, cameras, video, audio recorders and other digital recorders, users have been afforded the ability to record and transmit digital media within seconds.

[0004] With the advent of digital media, it has become increasingly easy to copy, counterfeit, falsify and misuse digital information of all kinds. This includes digital photographs, video & audio recordings of speech or musical performances, motion pictures and recordings of physical phenomena, such as meter readings or “black box” records. This digital media can be altered in ways that defy detection, audio recordings can be compressed and anonymously offered to the public with impunity, and time and date stamps on any of the media just listed can be easily changed with freely available tools.

[0005] An attendant problem is that of secure storage. While a flash memory card within these digital recording devices (in any of its currently popular forms) can hold hundreds of pictures, images, video and audio, the problem with securely storing, indexing and retrieving thousands of media files has still not been solved. When the works of intellectual property (music, software, images and movies, to name a few) are much more valuable than the equipment on which they reside, the temptation for theft and alteration becomes great.

[0006] Furthermore, this invention provides for the secure non-repudiation by embedding Certificate Authorities non-repudiation Digital Certificates of said digital files for forensic or other evidentiary purposes that are sent and received across said transmission networks. This works for any kind of media file – photographs, images, music, audio spoken word, video, physical phenomena – anything. Obvious applications range from taking a photograph, video clip to “black boxes” embedded in transportation facilities. Following an incident, information could be transmitted using the above schemes to a storage facility. Only authorized personnel could then retrieve the encrypted messages and return the data to clear text form.

## SUMMARY OF THE INVENTION

[0007] The present invention disclosed and claimed herein, in one aspect thereof, comprises an apparatus for recording image or other data in real time. The apparatus includes a capture device for capturing the image or other information. Once captured, a local verification device is operable to indelibly mark the captured image or other information with the date, time, location and information identifying the creator of the data. A transmitter is provided for transmitting the locally verified captured image or other information in real time to a secure storage facility. The capture device is operable, after the locally verified captured image or other information is transmitted to the secure storage facility, to receive and verify acknowledgment of the receipt of the transmitted locally verified captured image or other information to the storage facility.

## BRIEF DESCRIPTION OF THE DRAWINGS

[0008] For a more complete understanding of the present invention and the advantages thereof, reference is now made to the following description taken in conjunction with the accompanying Drawings in which:

[0009] Fig. 1 illustrates a block diagram of the overall operation of the system in accordance with the present disclosure;

[0010] Fig. 2 illustrates a diagrammatic view of the captured and encrypted file;

[0011] Fig. 3 illustrates a flow chart depicting the overall operation of the capture operation;

[0012] Fig. 4 illustrates a flow chart depicting the operation of the request operation for the start certificate;

[0013] Fig. 5 illustrates a flow chart depicting the operation of requesting information from the GPS; and;

[0014] Fig. 6 illustrates a flow chart depicting the operation of embedding information into the captured file;

[0015] Fig. 7 illustrates a flow chart depicting the operation of requesting the stop certificate;

[0016] Fig. 8 illustrates a flow chart depicting the encryption algorithm operation

## DETAILED DESCRIPTION OF THE INVENTION

[0017] Referring now to Fig. 1, there is illustrated a block diagram of the overall operation of the system in accordance with the present disclosure. The system generally is directed toward a capture device 102 that is operable to capture, in this embodiment, an image of an individual; for example, the individual denoted by the reference numeral 104. This can be any type of scene or any type of information that is captured. This could be a video segment, a still picture or an audio segment. It should be understood that the capture device 104 could capture any type of information, not just video information. As will be described herein below, the purpose of the system of the present disclosure will be to not only capture information but to store the information in a secure and certifiable manner such that it is non-repudiable. The capture device is controlled by a user through an input/output (I/O) interface 106. The image 104, in this example, will be captured in the form of a capture file 108 stored in a storage area 110, this being a buffer area. The capture device 102 could be a cell phone that has a video camera associated therewith, any type of device having a digital camera associated therewith, an audio system for capturing an audio file, etc. The phone, in one example, can capture and digitize the image, or even a video segment.

[0018] Once the captured image 108 is formed and temporarily stored, it then goes to the next step of the operation. In this step of the operation, a process block 112 is provided to obtain local certification. Local certification, in this example, is some certification that is viewed as providing information in such a manner that there is a high level of confidence in that information which is to be associated with the image as an integral part thereof and will, as described herein below, follow the image. For example, the information that is obtained will be time and date information and longitude and latitude information that is received from a GPS system (global positioning system), a conventional system. The time information, the date information and the longitude and latitude information are provided in such a manner that, when associated with the capture file 108, this provides some current validation that the file was created at that particular time and, at a later time, it could be identified by the fact that it has that information associated therewith. For example, a user could make a log, either printed or electronic of the image captured and, at a later time, by merely knowing what the time and data information was and the longitude and latitude information was, this would provide a higher degree of confidence that the

later viewed file and the original captured file was the same and had not been tampered with or had not been reproduced at a later time and location.

[0019] In order to provide this verification, the trusted entity is the GPS system, since this is a system that provides a time stamp and a longitude and latitude from the calibrated system. If this is implemented in such a manner that it is an integral part of the capture operation, i.e., it is integrated into the phone, for example, then a high degree of confidence is maintained that this was obtained basically at the time the capture was complete. The GPS system, as noted herein above, is a conventional system that utilizes a GPS receiver 114 that has an antenna 116 that is operable to receive information from a plurality of satellites 118. Typically, there can be anywhere from three to ten or more satellites from which information can be received to obtain an accurate location. Alternate techniques for recovering time, date and position information includes differential and Doppler analysis of very precise timing signals coming from a plurality of cellular/PCS base stations. A third technique for recovering time, date and position information includes retrieving information directly from the Mobility Management (MM) sub layer of the cellular protocol, where the mobile telephone service provider is a party to the transactions. Finally, another technique of retrieving accurate time and date information include use of a network time server.

[0020] The result of the local certification is a locally certified captured image 120 which is illustrated with the image and a time stamp, "TS," disposed on the edge thereof, this location by way of example only, as other methods of disposing this information are described herein below. This "TS" indicates that there is some information that is "embedded" into the captured file or captured image that is now part of the file. For example, as will be described in more detail herein below, there is a science of embedding information referred to as "Steganography" that allows information to be embedded in some expression of intellectual property (a photograph, a musical recording, or other expression,) such that (a) the information is hidden from casual observers and (b) the information is not easily altered or destroyed. One such type is a "water mark" that basically is disposed in the background of a document, for example. In images, there are encoding techniques such as "glifs" that can be disposed in the image which is an optical type encoding that appears as a random background to a viewer, but actually contains digitized information. The result is that the document, file image, etc., is indelibly marked with the date,

the time and the location, in addition to associating therewith information about the user in the form of a user ID, which is provided in a user ID block 122. The local certification block 112, therefore, is operable to merge the captured file 108, the GPS information as to time stamp and location and the user information into the single document 120. At this point, the document 120 is still a "clear" document such that it can be viewed by any individual. The image 120 is stored in a temporary image buffer 121.

[0021] After the document 120 has been created with the local certification, the system then compresses the file using any of a number of well-known methods. In the case of an image, the compression technique may be a lossy algorithm such as JPEG or (in the case of motion pictures) MPEG, or for a data set, the compression technique may be a lossless method such as Lempel-Ziv-Welch.

[0022] After compression, the file 120 is processed through an encryption operation wherein the file is first encrypted in accordance with predetermined encryption algorithms, this being performed in a block 124. The encryption, as will be described herein below, is a double encryption operation which wraps the local certified captured file with a first level of encryption 126 and a second level of encryption 128 to provide an encrypted document 130. This is then stored in a temporary storage buffer 132. The file 130 is then subjected to a non-repudiation certification process to acquire a Certificate of Authenticity (CA) from a certification authority 135, this certification authority 135 being a trusted third party that can "digitally sign" a file, image, etc. and provide a level of authenticity to that file. This is conventional technology. The document 130, in its encrypted form, is converted to a "hash" file and this hash file, which is a representation of the encrypted file, is sent to the certification authority 135 via a transmitter and antenna 136 along a wireless path, and received by an antenna 137 at the certification authority 135 location. Again, this is a wireless operation. The hash file is then signed and a combination hash file and certificate of authenticity is then sent back to the antenna 136 which is then stored in a temporary memory 133 as a certified document. This is illustrated with the attached certification authority certificate 139. This is the file that is sent to the secure storage facility, this being a file 130'.

[0023] After encryption, certification by the CA and compression, the encrypted file is then passed to

the transmitter 134 for transmission via the antenna 136 along a wireless path to a secure storage facility 138 having a receiving antenna 140 associated therewith. The secure storage facility 138 is a repository. In one embodiment, this repository 138 does nothing more than to store the image 130 in a large database 142 for access at a later time. Additionally, the secure storage facility 138 could be a trusted storage facility, which trusted storage facility has the ability to “unwrap” the encryption from the document 120 such that it can transmit the document 120 at a later time upon request. Alternatively, the secure storage facility 138 could merely be a place to store the information with secure measures as to restricting access to only authorized individuals. In that scenario, the secure storage facility 138 would not be able to decrypt the image 130 and would merely be able to transfer the image to the individual or entity authorized to access that information.

[0024] For access, a remote access site 144 is operable to send requests to the secure storage facility 138, identify themselves with the appropriate passwords to comply with the security procedures of the secure storage facility 138 and then have the image requested sent thereto. This image can then be stored in a memory 146 and decrypted with a decryption algorithm in a block 148 for storage of the decrypted file 120 in a storage space 150. This can then be extracted by a user for whatever purpose. In general, all of the encryption ensures that there has been no “tampering” with the file before it is decrypted. Once decrypted, then the time date stamp and location information, in addition to the user information, is still embedded in the picture, document, audio file, etc. that makes up the captured file to show that there was some local indelible certification that verifies the captured file as being authentic and which was embedded at the time of creation.

[0025] Referring now to Fig. 2, there is illustrated a diagrammatic view of the captured and encrypted file 130 which, as noted herein above, is comprised of the locally certified captured file 120 wrapped by the first layer of encryption 126 and the second layer of encryption 128. As will be described herein below, the first layer of encryption is a symmetrical encryption algorithm and the second layer 128 is an asymmetrical encryption layer 128. The symmetrical encryption layer is something that can be unwrapped merely by having access to various public keys. This is a fairly conventional PKI system. The second layer of encryption, the asymmetrical encryption layer, is a layer that requires a private key in order to extract this layer. Therefore, in order to gain access to the file at the second layer of

encryption, the individual must have the private key to unwrap the first layer and the other key to unwrap the second layer. Again, this will be described in more detail herein below.

[0026] Referring now to Fig. 3, there is illustrated a flow chart depicting the overall operation of the capture operation, which is initiated at a start block 302 and then proceeds to a function block 304 in order to allow the user to activate the capture device 102. The user activates the capture device 102 and then a capture operation is initiated at a block 306. Upon initiation of a capture, there is, in one embodiment, a “start” request sent out to the certification authority 135. The certification authority 135 receives the request generated at the block 308 for a certification certificate as to the “start” information that was sent to it. This can merely be the text “start” that is certified. This is sent back to the system during the capture operation. A decision block 310 indicates that this operation which will wait for the receipt of the certificate. However, during the time that this certificate is being generated, the capture is continuing. Once the program, after the start request is generated, then flows to a decision block 310 to wait for the completion of the capture operation. As soon as this is complete, the program flows along a “Y” path to a function block 312 in order to request the time, date, longitude, latitude information and then embed this information along with user information, as indicated by a function block 314. This is embedded into the captured file as described herein above. The program then flows to a function block 316 in order to request a “stop” certificate from the certification authority 135. In this operation, the certificate is requested prior to encryption such that the “clear” file can be certified prior to encryption with the certificate 139. However, the file could be encrypted first and then certified. The program then flows to an encryption block 318 to encrypt the file and then to a function block 320 to compress the file. This compressed file is then transmitted to the repository, as indicated by a function block 322 and then the program proceeds to an End block 324.

[0027] Referring now to Fig. 4, there is illustrated a flow chart depicting the operation of the request operation for the start certificate, as initiated at a block 402. The program then proceeds to decision block 404 in order to initiate the capture operation. When the capture operation is initiated, the program flows along a “Y” path to a function block 406 to send the “start” text to the certification authority 135. Of course, this could be a “hash” of a certain initial part of the capture file, but just the text would be sufficient. The program then flows to a decision block 410 to determine if the certificate has been

received for this “start” text and, when it has been received, the program will flow along the “Y” path to a function block 412 to store this received certificate in association with the captured file. Of course, this may not be disposed in association therewith until the capture is complete. Additionally, although not illustrated in this flow chart, the start time could also have time and date information as well as longitude and latitude information associated therewith such that there would be local certification of both the start time and the stop time which is received from a trusted authority, i.e., the GPS system. Once this information is determined as stored in association with the captured file, the program flows to a return block 414. Again, this information may merely be stored in a temporary buffer until the capture is complete.

[0028] Referring now to Fig. 5, there is illustrated a flow chart depicting the operation of requesting information from the GPS, which is initiated at a block 502. The program then flows to a function block 504 in order to access the GPS system. This, again, is a conventional operation which will obtain both accurate time information and location information. This access of information is indicated in a function block 506. The program then stores this information and flows back to a Return block 508.

[0029] Referring now to Fig. 6, there is illustrated a flow chart depicting the operation of embedding information into the captured file, which is initiated at a block 602. The program then flows to a function block 604 to initiate a steganography algorithm. The steganography operation is operable to permanently modify the captured file with the time/date information and longitude and latitude information as well as user ID information, this indicated at a function block 606. The program then flows to a function block 608 to store a modified captured file with this local certification information embedded therein. Again, this local certification information provides some level of authenticity to a “clear” file. The program then flows to a Return block 610.

[0030] Referring now to Fig. 7, there is illustrated a function block or a flow chart depicting the operation of requesting the stop certificate, which is initiated at a start block 702 and then proceeds to a function block 704 to create the “hash” file of a modified capture file. This hash file is then sent to the certification authority 135, as indicated by a function block 706. The program then flows to decision block 708 to wait for the receipt of the certificate and, once received, flows to a function block 710 to

basically sign the modified capture file and associate with the modified capture file a certificate of authority. Since the hash file is a digital representation of the actual captured file, the actual capture file does not have to be transmitted to the certification authority 135. The reason for this is that one would like to prevent the transmission over any wireless link of "clear" information. As such, the hash file has no discernable information associated therewith and, as such, it only has meaning when associated with the original file from which it was generated, since the algorithm for generating a hash file will clearly identify the two. As such, the certificate generated by the certification authority 135 is sufficient to ensure that a trusted authority has in fact verified the authenticity of the file, this indicated by a function block 712 wherein the captured file is signed and then the program flows to a Return block 716.

[0031] Referring now to Fig. 8, there is illustrated a flow chart depicting the encryption algorithm operation, which is initiated at a block 802 and then proceeds to a function block 804. This is the operation wherein symmetrical encryption is utilized with a "public and private key system." The symmetrical encryption is an operation in which a plaintext message is transformed by a well-known algorithm operating under control of a key. The key is a short (less than 1000 bits, usually) data string that instructs the encryption algorithm how to transform the plaintext into an unreadable form called ciphertext. This type of encryption is called "symmetrical" because the same key that is used to encrypt the plaintext is used to decrypt the cyphertext, resulting in a plaintext file once again.

[0032] After encryption in the "first layer," the program then flows to function block 806 to create the first cyphertext file. This first cyphertext file is then processed with an asymmetrical encryption algorithm, as indicated by a function block 808 to further encrypt or protect the captured file. The second general type of cryptosystem is asymmetrical encryption. This encryption scheme uses mathematical functions called one-way or trapdoor functions that are easy to perform but extremely difficult to reverse. Examples of these one-way functions are factoring large composite numbers (two large numbers are easy to multiply, but finding the two large numbers given the product alone is difficult) and the discrete logarithm problem (raising a number to a power modulo some value is easy, but finding the number given the result is difficult.) In an asymmetrical cryptosystem, one key (referred to as the public key) is used to encrypt the plaintext and a second, related key (called the private key) is used to decrypt the ciphertext. In a public-key encryption scheme, it is common to publish the public

key. In this way, anyone can send a secure message, but only the holder of the private key can decrypt the message and reveal the plaintext.

[0033] Asymmetrical cryptosystems have another use as well: by encrypting a file under his or her private key, a party can prove that he or she is the author of the message. If others can decrypt the file using the associated public key, then nobody but the holder of the private key could have created the message. This leads to properties favorable to the present invention: proof of ownership and non-repudiation. The result of the asymmetrical encryption step will be the creation of the second cyphertext file as an encrypted stamped and certified captured file, as indicated by function block 810. The program then proceeds to a Return block 812.

[0034] To illustrate how the system of the present disclosure operates, one example of an application of the capture device 102— a wireless digital camera — will be described.

[0035] The user takes a picture, video, audio, or acquires any other data set, or any combination of these. The apparatus then sends a request to a certificate authority to obtain a certification of the time and date of the recording. This certificate, as well as time, date and location information obtained from the GPS receiver or other techniques for determining this information, as well as an identifying number unique to the wireless digital video camera, is steganographically encoded onto the image and/or audio files.

[0036] The image is now marked, but it is still “in the clear.” That is, anyone who gains access to the image file will be able to reproduce the image. It must now be secured so that unauthorized parties cannot view the image.

[0037] After compression, the next step is to encrypt the file in such a way that the file cannot be used without access to a secret key.

[0038] Once the image file has been indelibly marked and compressed, and it is about to be encrypted using a symmetrical cryptosystem, a decision must be made as to what key to use. There are several

methods of establishing a key. The first is to have a single, fixed key assigned to the wireless digital recorder (i.e. camera) at the factory. The problem with this method is that if this key becomes compromised, then all images taken by the wireless digital recorder (i.e. camera) are compromised. A second method is to create a new, random key each time a photograph is taken, and store the table of keys in the wireless digital recorder (i.e. camera) for subsequent download. This, although feasible, may be undesirable for the same reason that storing the images themselves in the wireless digital recorder (i.e. camera) is undesirable: memory in the wireless digital recorder (i.e. camera) is fragile, and if the keys are lost, the images are useless.

[0039] Instead, a preferred method of key management is used. In this scheme, the serial number of the wireless digital recorder (i.e. camera) and other pertinent information that can be recovered without recovering the file (like the filename, the time and date, etc.) are securely hashed. Hashing refers to a practice of creating a short dataset that represents a larger dataset. For example, if one were to assign all the letters in a document a number (A=1, B=2, etc.), add those numbers together modulo 26, one would come up with a single number between 0 and 25. If any letter in the document changed, the result of the function would change as well, and thus could be used as an indication that the document had changed. In a way, the short dataset (the modulo sum) would stand in for the larger dataset (the document). Note that the short dataset cannot be used to reproduce the document, but that changing the document in a way that doesn't affect the modulo sum is difficult.

[0040] Hashing works in just this way, but with much larger numbers. In the disclosed system, the serial number is hashed with other information to create a key. If the key is compromised (by technical or legal means) then no other photograph taken by the wireless digital recorder (i.e. camera) is compromised. It is impossible – not just difficult – to go from the hashed key to the source material, in the same way it is impossible to deduce this document from one modulo sum character.

[0041] Now the file is encrypted, and only the holder of the secret key can unlock the file. Two more steps remain before the file is transmitted to the secure storage facility. First, the entire encrypted file is passed through a message authentication algorithm, which produces a hash (similar to the way the symmetrical encryption key was calculated, above) over the whole file. In this way, if any byte of the

message file is corrupted in transmission, it will be discovered. The file is then encrypted using an asymmetrical cryptosystem under the user's private key, effectively signing the file.

[0042] Finally, identifying information is added to the (now doubly) encrypted file, and the file is encrypted again – this time, under the storage facility's public key. Now, observe the properties of the file thus created:

- The file is secure. Nobody but the storage facility can open the outer wrapper.
- The file is anonymous to casual observers. There is no identifying information outside of the outer wrapper.
- The file is signed. The storage facility can open the outer wrapper and discover an identifier of the party who claims to have created the file.
- The signature is irrefutable and cannot be repudiated. The storage facility can look up the public key of the party claiming to be the author of the file, and can attempt to open the middle wrapper. Inside, they will find an encrypted file and a hash of the file. If the calculated hash matches the given hash, then the photograph without question belongs to that party.
- Even after two wrappers have been removed, the picture is still secret. The storage facility keeps only encrypted files. They have no means of removing the final wrapper.

[0043] Should it become necessary to prove the authenticity of the photograph, the storage facility 138 can testify to all the above facts. Additionally, the originator of the photograph is the only one who can unlock the inner wrapper and produce the photograph. Finally, the photograph itself is steganographically marked, and this final information is clinching proof that the provenance of the photograph is accurate.

[0044] To return to the example wherein the picture is ready for transmission at this point, the wireless digital recorder (i.e. camera) attempts to connect to the server at the secure storage facility 138 or other recipients who have access the network (i.e. PDA's, other wireless digital devices) using any of a number of well-known wireless methods. Among these are data channels associated with IS-95 CDMA, IS-136 TDMA, CDPD, GSM as well as purely data paths such as 802.11b. The exact mechanism of data transmission is not germane.

**[0045]** However the data is transmitted, the storage facility 138 receives the triply-encrypted data file and performs the following steps:

- Remove the outer wrapper and extract an encrypted file and plain-text subscriber identification.
- Look up the subscriber information and recover his/her public key.
- Remove the middle wrapper using the public key to reveal an encrypted file and a hash value.
- Pass the encrypted file through a message digest algorithm to produce a computed hash.
- If the computed hash does not match the received hash, send a negative acknowledge and discard the file; otherwise...
- Calculate a message digest of (1) the received hash, (2) the time and date, and (3) a random number.
- Return an affirmative acknowledgment and a certificate containing the message digest calculated in (6), above.
- Store the encrypted photograph along with the received time and date and the random number produced in (6). In this way, if the certificate is ever challenged, the storage facility will be able to verify that it sent the certificate.

**[0046]** The user can also transmit these files over various networks to other recipients (PDA's, cell camera phones, "IP Addresses, E-mail to name a few) for their review and storage. However the users' unique identity and other certificates described in this document are embedded within the file(s). The wireless digital recorder (i.e. camera), upon receipt of the certificate, transmits an acknowledgment and removes the photograph from its temporary store. The certificate can be stored or discarded – it is not required to retrieve the photograph. If stored, it becomes further evidence of the provenance of the photograph.

**[0047]** Image retrieval from the storage facility 138 is simple. At login, the storage facility presents a random string encrypted under the user's public key. The user must decrypt the string and re-encrypt it under the storage facility's public key. Only the holder of the secret key can do this...and it proves beyond doubt to the storage facility that they are communicating with the owner of the photograph.

[0048] Once identity is established, the user can download any file from the storage facility. Once downloaded, the user can open the final wrapper and extract the image.

[0049] Again, this works for any kind of media file – photographs, images, music, audio spoken word, video, physical phenomena – anything. An obvious application would be in “black boxes” embedded in transportation facilities. Following an accident, information could be transmitted using the above schemes to a storage facility. Only authorized personnel could then retrieve the encrypted messages and return the data to cleartext form.

[0050] Some of the features provided by the system of the present disclosure are as follow:

- An apparatus for the purpose of recording image or other data in real time; indelibly marking the data with the date, time, location and information identifying the creator of the data; transmitting the data in real time to a storage facility; and receiving and verifying acknowledgment of the receipt of the data from the storage facility. The apparatus consists of an image-recording device or other data recording device, a geographical position and time-of-day determination device, a data processing unit and a communication device.
- Additionally the image-recording device is a digital camera.
- Additionally the image-recording device is a video camera.
- Additionally where the digital image capture device is an image scanner.
- Additionally the digital image capture device is a facsimile machine.
- Additionally the data-recording device is a digital voice recorder.
- Additionally the data-recording device is a real-time data acquisition system.
- Additionally the geographical position and time-of-day determination device is a GPS receiver.
- Additionally the data processing unit is a microcontroller.
- Additionally the data processing unit is a field-programmable gate array.
- Additionally the data processing unit is an application-specific integrated circuit.
- Additionally the communication device is a cellular telephone chipset.
- A method is also provided of recording images, sounds or other data and indelibly marking the images, sounds, or other data with the date, time, location, authentication certificate, and information identifying the creator of the data.

- The method further includes the step in which the authentication certificate is obtained by polling a certificate authority by means of the communication device.
- The method further includes the step in which the method of indelibly marking images is steganography.
- The method further includes the step in which the method of indelibly marking sounds is watermarking.
- Another method is provided of encrypting images and other data such that unauthorized parties cannot render the images and other data in usable form; the images and other data cannot be repudiated by the creator; and that date, time, location and creator metadata can be verified by third parties.
- The method further includes the step in which the image or other data is first compressed using a well-known compression algorithm, producing a compressed image or other data.
- The method further includes the step in which the compression algorithm is the Lempel-Ziv-Welch algorithm.
- The method further includes the step in which the compression algorithm is the JPEG algorithm.
- The method further includes the step in which the compression algorithm is the MPEG algorithm.
- The method further includes the step in which the compressed image or other data is encrypted under a symmetrical, single-key cryptosystem.
- The method further includes the step in which the cryptosystem is DES.
- The method further includes the step in which the cryptosystem is IDEA.
- The method further includes the step in which the cryptosystem is Triple-DES.
- The method further includes the step in which the cryptosystem is AES.
- The method further includes the step in which the image or other data, having been encrypted under the symmetrical cryptosystem, is then applied to a message digest algorithm.
- The method further includes the step in which the output data of the message digest algorithm are then appended to the symmetrically encrypted data.
- The method further includes the step in which the message digest algorithm is the Secure Hash Algorithm.
- The method further includes the step in which the image or other data, having been symmetrically encrypted and having a message digest appended is then further encrypted using an

asymmetrical (public-key) algorithm.

- The method further includes the step in which the image or other data is encrypted using the creator's private key.
- The method further includes the step in which the asymmetrical algorithm is the RSA algorithm.
- The method further includes the step in which the image or other data, having been encrypted under the symmetrical algorithm and the asymmetrical algorithm, is then augmented with personal identifying information belonging to the creator of the data.
- The method further includes the step in which the personal identifying information is a serial number.
- The method further includes the step in which the image or other data, having been encrypted and with said personal identifying information appended is then further encrypted using a public-key encryption algorithm.
- A storage facility operation is also provided for the purpose of receiving and storing images, audio and other data from a multiplicity of information sources.
- The method further includes the step in which the encryption is performed under the public key belonging to the storage facility.
- The method further includes the step in which the public-key encryption algorithm is the RSA algorithm.
- The method further includes the step in which the image or other data encrypted according to the method of above under the public key belonging to the storage facility is then transmitted to the storage facility using a transmission medium.
- The method further includes the step in which the transmission medium is cellular digital packet data.
- The method further includes the step in which the transmission medium is a CDMA data channel.
- The method further includes the step wherein the storage facility verifies the origin of information received that has been transmitted according to the above methods.
- The method further includes the step in which the information received is decrypted under the private key belonging to the storage facility.

- The method further includes the step in which the decrypted information consists of an encrypted data set and identifying information.
- The method further includes the step in which the identifying information is used as an index into a database that contains the public encryption keys of all parties authorized to store information in the storage facility.
- The method further includes the step in which the identifying information is used to locate a unique public key contained in the data base of and belonging to the purported originator of the data.
- The method further includes the step in which the key obtained by the above methods is used to decrypt the encrypted data set of, creating a decrypted data set.
- The method further includes the step in which the decrypted data set consists of a symmetrically encrypted data set and a received message digest.
- The method further includes the step in which the symmetrically encrypted data set is presented to a message digest algorithm to produce a computed message digest.
- The method further includes the step in which the received message digest is compared to the computed message digest.
- The method further includes the step in which verification of the message is determined to be successful if the received message digest and the computed message digest are identical.
- The method further includes the step of transmitting an acknowledgment of receipt to the originator of the image or other data.
- The method further includes the step in which the acknowledgment of receipt consists of the received message digest encrypted under the private key of the storage facility and the public key of the originator.
- The method further includes the step in which the certificate authority is a public certificate authority.
- The method further includes the step in which the certificate authority is a private certificate authority.
- The method further includes the step in which the certificate authority is a government agency.
- The method further includes the step in which the time, date and location information is obtained from the GPS receiver.
- The method further includes the step in which the time, date and location information is derived

from signaling obtained from the cellular telephone chipset .

- The method further includes the step in which the time, date and location information is derived directly from information contained in the MM layer of the mobile telephone service provider.
- The method further includes the step in which the time and date information is derived from a network time server.
- The method further includes the step where the secure server or image data repository is Data Base server.
- The method further includes the step where the secure server or image data repository is Web server.
- The method further includes the step where the secure server or image data repository is e-mail server.
- The method further includes the step where the secure server or image data repository is FTP server
- The method further includes the step for securely retrieving data stored at the storage facility.
- The method further includes the step in which the method is a challenge-response mechanism.
- The method further includes the step in which the request includes the identity of the requestor and the identity of the data set to be retrieved.
- The method further includes the step in which the storage facility creates a random bit stream as a challenge.
- The method further includes the step in which the storage facility determines the public key of the requestor by means of looking up the public key in the database.
- The method further includes the step in which the storage facility encrypts the random bit stream with the public key belonging to the requestor.
- The method further includes the step in which the storage facility transmits the encrypted random bit stream to the requestor.
- The method further includes the step in which the requestor decrypts the random bit stream using the private key corresponding to the public key under which the bit stream was encrypted.
- The method further includes the step in which the recovered random bit stream is then re-encrypted in the public key belonging to the storage facility.
- The method further includes the step in which the re-encrypted random bit stream is transmitted

back to the storage facility.

- The method further includes the step in which the storage facility then decrypts the random bit stream using its private key.
- The method further includes the step in which the storage facility determines whether the requestor is authentic by comparing the random bit stream recovered from the response of the requestor and the random bit stream .
- The method further includes the step in which the storage facility transmits the requested data set only if the random bit streams match.
- The method further includes the step in which the method is biometric.
- The method further includes the step in which the storage facility sends a zero knowledge challenge to the requestor.
- The method further includes the step in which the requestor performs a biometric measurement to determine the response to the zero-knowledge challenge.
- The method further includes the step in which the requestor returns the requested data set only if some number of challenges is answered correctly.
- The method further includes the step in which the method is by means of a password or passphrase.
- The method further includes the step in which the method is by means of an electronic key or other electronic identification device.

**[0051]** With the disclosed system, this provides for a method of storing, cataloging, viewing, playback and printing of images, video, audio and photographs change as well. Instead of relying on photo finishers, anyone with an inexpensive printer can reproduce images, anyone with a CD reader/writer can reproduce audio, and anyone with a DVD player/recorder can reproduce both images and audio.

**[0052]** Additionally, instead of a fireproof safe, image, video, audio and photograph storage involves digital media. And, instead of couriers and the mail, transmitting images, video, audio and photographs from one place to another is likely to involve the Internet.

[0053] This new world of opportunities has its problems as well. Once images, video, audio and photographs are in the digital domain, there are opportunities to modify these so that it no longer represents the events that actually occurred. Digital cameras or other digital recorders at the time of this submission, typically include a clock of dubious accuracy that can, in any event, be set back or forward to make it seem as though an event occurred at a time other than the actual time of the event. And the metadata – the time, date, and location of the images, video, audio and photographs – is not stored using any secure method. Anyone knowledgeable in the field can modify the metadata to make the images, video, audio and photographs appear that it was taken at a time and place other than the real time and place.

[0054] Another problem solved with the system of the present disclosure is that of storage. For many users (photographers, musicians, forensic, video / audio personnel, governmental, military personnel, public service, professional and non professional personnel and others) the value of the images, video, audio and photographs taken far exceeds the value of the equipment used to take them. For these users, it is important that the images, video, audio and photographs themselves be transported to a secure location at the earliest possible opportunity. Digital recording devices (i.e. digital cameras and other digital recording devices) rely on memory cards that contain non-volatile solid-state memory that, while robust for a solid-state device, is easily damaged by mechanical shock or static electricity. Unlike film, in which a defect may only cause a minor blemish in the image, a single defect in the memory card of a digital recording device may be enough to render all the information on the card useless.

[0055] It is noted that the images, video, audio and photographs not be disclosed to an unauthorized third party. While traditional analog film images, video and audio recordings can be physically locked into a secure facility, digital images, audio, and video reside on computers. These computers can be the subjects of network attacks and information on them can be compromised in two ways. First, a knowledgeable opponent can read information from an internet-connected computer – that is, an opponent can view images, video, audio and photographs he or she is unauthorized to view. Second, a knowledgeable opponent can obtain write permission and modify the images, video, audio and photographs in a way that is difficult to detect.

[0056] Finally, the user is provided the ability to attach, mix, and modify media files easily and indelibly mark each image, video, audio, photograph or media file as his or her own work, to eliminate the possibility of plagiarism and to provide a certificate authority while wirelessly transmitting said media files for secure storage or to another recipient or source.

[0057] In the days of film cameras (analog), security usually meant placing the negatives into a photo safe. Prints made from the negatives could be marked with an identifier that clearly indicated the pedigree of the photograph. Those who would use the photograph without permission of the owner would be subject to a copyright infringement suit – and it would be sufficient evidence in court for the user to produce the negatives and testifies that, in fact, he or she took the photographs.

[0058] With the advent of digital media and the proliferation of the Internet, images, video, audio, photographs and other forms of digital documents stored on digital computers are no longer secure. This invention addresses all of these concerns. It provides a mechanism for recording, attaching, mixing, appending to, modifying images, video, audio and photographs, marking the images, video, audio and photographs indelibly with a provable time, date, location and identity of the individual taking the images, video, audio and photographs. It then provides a means to transport the images, video, audio and photographs to a secure, off-site storage facility and to obtain positive confirmation that the transmission occurred error-free. It provides a method for securely rendering the image, video, and audio and photograph useless to anyone but the original user. Finally, it provides the ability to demonstrate, with legal certainty, that the image, video, audio and photograph was taken at the location and at the time indicated, and that the image or audio file has not been altered, as well as, tracks ongoing changes made by the originator or other user identities within the original file.

[0059] Although the preferred embodiment has been described in detail, it should be understood that various changes, substitutions and alterations can be made therein without departing from the spirit and scope of the invention as defined by the appended claims.
